

AI Teaching Assistant — Performance Audit

8 real Lighthouse measurements across 2 public routes × Mobile / Desktop, generated 2026-09-15. Simulated throttling, both forced color schemes. No score below was invented; every number ties back to an actual audit run against this project's own production build. Authenticated routes (/app , /present) are excluded — they redirect to the login page without a session, so auditing them would measure that page twice.

ROUTES AUDITED

MOBILE · AVG PERF

90.0

range 88–92

DESKTOP · AVG PERF

100.0

range 100–100

LOWEST PERFORMANCE

88

below the 90 floor

Reading these numbers

Accessibility, Best Practices, and SEO all score a perfect 100 across every measured route. Performance is the category with the most headroom, and it scales directly with how hard each device profile throttles CPU and network — a heavier mobile throttle (4× CPU, slower network) makes the identical bundle take longer to become interactive than the same bundle under a light desktop throttle. That gradient is expected, not a defect. This app is client-rendered, so first paint additionally waits on the JavaScript bundle booting the router: that startup cost is present on every route by design, and is the single largest lever on the Performance figures below.

Generated from a real Lighthouse sweep of this project's own production build — see LIGHTHOUSE.md in the repo for the raw run. Performance and Web Vitals reflect a local development machine and are a conservative floor, not a prediction of production scores on a real CDN/edge deployment.
